Activity 6.1 Decision Trees

Consider the task of predicting whether children are likely to be hired to play members of the Von Trapp Family in a production of The Sound of Music, based on these data:

height	hair	eyes	hired
short	blond	blue	+
tall	red	blue	+
tall	blond	blue	+
tall	blond	brown	_
short	dark	blue	_
tall	dark	blue	_
tall	dark	brown	_
short	blond	brown	_

a. Compute the information (entropy) gain for each of the three attributes (height, hair, eyes) in terms of classifying objects as belonging to the class, + or -.

There are 3 objects in class '+' and 5 in '-', so the entropy is:

Entropy(parent) =
$$\Sigma_i P_i \log_2 P_i = -(3/8)\log(3/8) - (5/8)\log(5/8) = 0.954$$

Suppose we split on height:

Of the 3 'short' items, 1 is '+' and 2 are '-', so Entropy(short) = -(1/3)log(1/3) - (2/3)log(2/3) = 0.918

Of the 5 'tall' items, 2 are '+' and 3 are '-', so Entropy(tall) = -(2/5)log(2/5) - (3/5)log(3/5) = 0.971

The average entropy after splitting on 'height' is Entropy(height) = (3/8)(0.918) + (5/8)(0.971) = 0.951

The information gained by testing this attribute is: 0.954 - 0.951 = 0.003 (i.e. very little)

If we try splitting on 'hair' we find that the branch for 'dark' has 3 items, all '-' and the branch for 'red' has 1 item, in '+'. Thus, these branches require no further information to make a decision. The branch for 'blond' has 2 '+' and 2 '-' items and so requires 1 bit. That is,

Entropy(hair) = (3/8)(0) + (1/8)(0) + (4/8)(1) = 0.5

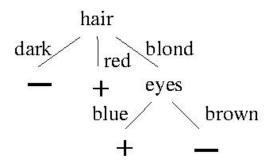

and the information gained by testing hair is 0.954 - 0.5 = 0.454 bits.

By a similar calculation, the entropy for testing 'eyes' is (5/8)(0.971) + (3/8)(0) = 0.607, so the information gained is 0.954 - 0.607 = 0.347 bits.

Thus 'hair' gives us the maximum information gain.

b. Construct a decision tree based on the minimum entropy principle.

Since the 'blond' branch for hair still contains a mixed population, we need to apply the procedure recursively to these four items. Note that we now only need to test 'height' and 'eyes' since the 'hair' attribute has already been used. If we split on 'height', the branch for 'tall' and 'short' will each contain one '+' and one '-', so the entropy gain is zero. If we split on 'eyes', the 'blue' brach contains two '+'s and the 'brown' branch two '-'s, so the tree is complete:

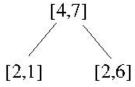

Activity 6.2 Laplace Pruning

The Laplace error estimate for pruning a node in a Decision Tree is given by:

$$E = 1 - \frac{n+1}{N+k}$$

where N is the total number of items, n is the number of items in the majority class and k is the number of classes. Given the following subtree, should the children be pruned or not? Show your calculations.

Error(Parent) =
$$1 - (7+1)/(11+2) = 1 - 8/13 = 5/13 = 0.385$$

Error(Left) =
$$1 - (2+1)/(3+2) = 1 - 3/5 = 2/5 = 0.4$$

Error(Right) =
$$1 - (6+1)/(8+2) = 1 - 7/10 = 3/10 = 0.3$$

Backed Up Error =
$$(3/11)*(0.4) + (8/11)*(0.3) = 0.327 < 0.385$$

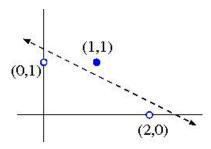

Since Error of Parent is larger than Backed Up Error ⇒ Don't Prune

Activity 6.3 Perceptron Learning

1. Construct by hand a Perceptron which correctly classifies the following data; use your knowledge of plane geometry to choose appropriate values for the weights w_0 , w_1 and w_2 .

Training Example	x_1	x ₂	Class
a.	0	1	-1
b.	2	0	-1
c.	1	1	+1

The first step is to plot the data on a 2-D graph, and draw a line which separates the positive from the negative data points:

This line has slope -1/2 and x_2 -intersect 5/4, so its equation is:

$$x_2 = 5/4 - x_1/2$$
,
i.e. $2x_1 + 4x_2 - 5 = 0$.

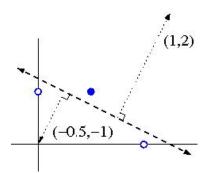

Taking account of which side is positive, this corresponds to these weights:

$$w_0 = -5$$

$$w_1 = 2$$

$$w_2 = 4$$

Alternatively, we can derive weights $w_1=1$ and $w_2=2$ by drawing a vector normal to the separating line, in the direction pointing towards the positive data points:

The bias weight w_0 can then be found by computing the dot product of the normal vector with a perpendicular vector from the separating line to the origin. In this case $w_0 = 1(-0.5) + 2(-1) = -2.5$

(Note: these weights differ from the previous ones by a normalizing constant, which is fine for a Perceptron)

2. Demonstrate the Perceptron Learning Algorithm on the above data, using a learning rate of 1.0 and initial weight values of

$$w_0 = -0.5$$

$$w_1 = 0$$

$$w_2 = 1$$

In your answer, you should clearly indicate the new weight values at the end of each training step.

Iteration	\mathbf{w}_0	\mathbf{w}_1	$ \mathbf{w}_2 $	Training Example	x ₁	x ₂	Class	$s=w_0+w_1x_1+w_2x_2$	Action
1	-0.5	0	1	a.	0	1	-	+0.5	Subtract
2	-1.5	0	0	b.	2	0	-	-1.5	None
3	-1.5	0	0	c.	1	1	+	-1.5	Add
4	-0.5	1	1	a.	0	1	-	+0.5	Subtract
5	-1.5	1	0	b.	2	0	-	+0.5	Subtract
6	-2.5	-1	0	c.	1	1	+	-3.5	Add
7	-1.5	0	1	a.	0	1	-	-0.5	None
8	-1.5	0	1	b.	2	0	-	-1.5	None
9	-1.5	0	1	c.	1	1	+	-0.5	Add
10	-0.5	1	2	a.	0	1	-	+1.5	Subtract
11	-1.5	1	1	b.	2	0	-	+0.5	Subtract
12	-2.5	-1	1	c.	1	1	+	-2.5	Add
13	-1.5	0	2	a.	0	1	-	+0.5	Subtract
14	-2.5	0	1	b.	2	0	-	-2.5	None
15	-2.5	0	1	c.	1	1	+	-1.5	Add
16	-1.5	1	2	a.	0	1	-	+0.5	Subtract
17	-2.5	1	1	b.	2	0	-	-0.5	None
18	-2.5	1	1	c.	1	1	+	-0.5	Add
19	-1.5	2	2	a.	0	1	-	+0.5	Subtract
20	-2.5	2	1	b.	2	0	-	+1.5	Subtract
21	-3.5	0	1	c.	1	1	+	-2.5	Add
22	-2.5	1	2	a.	0	1	-	-0.5	None
23	-2.5	1	2	b.	2	0	-	-0.5	None
24	-2.5	1	2	c.	1	1	+	+0.5	None

Activity 6.5 Evolution (COMP3411/9814 only)

Consider the following four algorithms applied to the task of searching through the space of bitstrings of length 20 to find the bitstring which maximizes a given fitness function:

- a. completely random search
- b. hillclimbing
- c. genetic algorithm (GA) using mutation only (no crossover)
- d. genetic algorithm using one-point crossover as well as mutation

For concreteness, let's assume that the GA has a population of 200, with 100 individuals replaced at each generation.

For each of the fitness functions listed below, which of the four algorithms would find the solution fastest? which would be slowest? or would two of them take about the same amount of time?

- 1. f(x) =the number of 1's in x.

0, otherwise.

the number of 1's in x, otherwise.

- 4. f(x) = 14, if x contains 7 consecutive 1's **and** 7 consecutive 0's,
 - 7, if x contains 7 consecutive 1's **or** 7 consecutive 0's,
 - 0, otherwise.
 - 1. This fitness landscape presents a nice "hill" to climb. Hillclimbing would find the solution much faster than random search, and so would the genetic algorithm (with or without crossover)
 - 2. This is called a "needle in a haystack" problem. The fitness landscape is completely flat, until you randomly stumble upon the solution. All four algorithms would take about the same amount of time.
 - 3. This is called a "deceptive" landscape. The slope tends to draw you **away** from the global maximum, and towards a local maximum. In this case, random search would find the solution faster than either hillclimbing or the GA.
 - 4. In this case, the GA with crossover would be fastest, GA without crossover would be somewhat slower, hillclimbing would be slower still and random search would be slowest. The strings of 7 consecutive 1's and 7 consecutive 0's behave as "building blocks", which independently increase their prevalence in the population and are then combined, through crossover, into a single individual.
